

Note: You must be able to identify which techniques you need to use. For example:

Integration:

- * Integration by substitution
- * Integration by parts
- * Integration by partial fractions

Note: Partial fractions are also used in ch 6 for a different application.

For differential equations:

Is the differential equation 1rst order or 2nd order?

If 2nd order: Section 3.1, solve $ay'' + by' + cy = 0$.

Guess $y = e^{rt}$.

$$ar^2e^{rt} + bre^{rt} + ce^{rt} = 0 \text{ implies } ar^2 + br + c = 0,$$

Need to have two independent solutions.

If $y = \phi_1, y = \phi_2$ are solutions to a LINEAR HOMOGENEC differential equation, $y = c_1\phi_1 + c_2\phi_2$ is also a solution

If 1st order: Is the equation linear or separable or ?

Solving first order differential equation:

Method 1 (sect. 2.2): Separate variables.

Method 2 (sect. 2.1): If linear $[y'(t) + p(t)y(t) = g(t)]$, multiply equation by an integrating factor $u(t) = e^{\int p(t)dt}$.

$$\begin{aligned} y' + py &= g \\ y'u + upy &= ug \\ (uy)' &= ug \\ \int (uy)' &= \int ug \\ uy &= \int ug \\ \text{etc...} \end{aligned}$$

Method 3 (sect. 2.4): Solve Bernoulli's equation,

$$y' + p(t)y = g(t)y^n,$$

when $n > 1$ by changing it to a linear equation by substituting $v = y^{1-n}$

direction field = slope field = graph of $\frac{dy}{dt}$ in t, v -plane.

*** can use slope field to determine behavior of v including as $t \rightarrow \infty$.

Equilibrium Solution = constant solution
stable, unstable, semi-stable.

Section 2.4: Existence and Uniqueness.

In general, for $y' = f(t, y)$, $y(t_0) = y_0$, solution may or may not exist and solution may or may not be unique.

But we have 2 theorems that guarantee both existence and uniqueness of solutions under certain conditions:

1st order LINEAR differential equation:

Thm 2.4.1: If $p : (a, b) \rightarrow R$ and $g : (a, b) \rightarrow R$ are continuous and $a < t_0 < b$, then there exists a unique function $y = \phi(t)$, $\phi : (a, b) \rightarrow R$ that satisfies the initial value problem

$$\begin{aligned} y' + p(t)y &= g(t), \\ y(t_0) &= y_0 \end{aligned}$$

1st order differential equation (general case):

Thm 2.4.2: Suppose $z = f(t, y)$ and $z = \frac{\partial f}{\partial y}(t, y)$ are continuous on $(a, b) \times (c, d)$ and the point $(t_0, y_0) \in (a, b) \times (c, d)$, then there exists an interval $(t_0 - h, t_0 + h) \subset (a, b)$ such that there exists a unique function $y = \phi(t)$ defined on $(t_0 - h, t_0 + h)$ that satisfies the following initial value problem:

$$y' = f(t, y), \quad y(t_0) = y_0.$$

Note the initial value problem

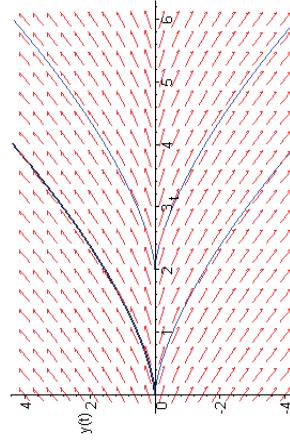

$$y' = y^{\frac{1}{3}}, \quad y(0) = 0$$

has an infinite number of different solutions.

$$\begin{aligned} y^{-\frac{1}{3}} dy &= dt \\ \frac{3}{2} y^{\frac{2}{3}} &= t + C \\ y &= \pm \left(\frac{2}{3}t + C\right)^{\frac{3}{2}} \\ y(0) &= 0 \text{ implies } C = 0 \end{aligned}$$

Thus $y = \pm \left(\frac{2}{3}t\right)^{\frac{3}{2}}$ are solutions.

$y = 0$ is also a solution, etc.

Compare to Thm 2.4.2:

$f(t, y) = y^{\frac{1}{3}}$ is continuous near $(0, 0)$
 But $\frac{\partial f}{\partial y}(t, y) = \frac{1}{3}y^{-\frac{2}{3}}$ is not continuous near $(0, 0)$
 since it isn't defined at $(0, 0)$.

Section 2.4 example: $\frac{dy}{dt} = \frac{1}{(1-t)(2-y)}$

$F(y, t) = \frac{1}{(1-t)(2-y)}$ is continuous for all $t \neq 1, y \neq 2$

$$\frac{\partial F}{\partial y} = \frac{\partial \left(\frac{1}{(1-t)(2-y)} \right)}{\partial y} = \frac{1}{(1-t)} \frac{\partial (2-y)^{-1}}{\partial y} = \frac{1}{(1-t)(2-y)^2}$$

$\frac{\partial F}{\partial y}$ is continuous for all $t \neq 1, y \neq 2$

Thus the IVP $\frac{dy}{dt} = \frac{1}{(1-t)(2-y)}, y(t_0) = y_0$ has a unique solution if $t_0 \neq 1, y_0 \neq 2$.

Note that if $y_0 = 2$, $\frac{dy}{dt} = \frac{1}{(1-t)(2-y)}, y(t_0) = 2$ has two solutions if $t_0 \neq 1$ (and if we allow vertical slope in domain). Note normally our convention will be to NOT allow vertical slope in domain of solution).

Note that if $t_0 = 1$, $\frac{dy}{dt} = \frac{1}{(1-t)(2-y)}, y(1) = y_0$ has no solutions.

Find domain: $2ln|1-t| + C \geq 0 \ \& \ t \neq 1 \ \& \ y \neq 2$

NOTE: the convention in this class to choose the largest possible connected domain where tangent line to solution is never vertical.

$2ln|1-t| \geq -C$ and $t \neq 1$ and $y \neq 2$ implies

$|1-t| > -\frac{C}{2}$ Note: we want to find domain for this C and thus this C can't swallow constants).

$|1-t| > e^{-\frac{C}{2}}$ since e^x is an increasing function.

$$1-t < -e^{-\frac{C}{2}} \text{ or } 1-t > e^{-\frac{C}{2}}$$

$$\text{Domain: } \begin{cases} t > e^{-\frac{C}{2}} + 1 & \text{if } t_0 > 1 \\ t < -e^{-\frac{C}{2}} + 1 & \text{if } t_0 < 1. \end{cases}$$

$$(1, 1 / ((1-t)(2-y))) / sqrt(1 + 1 / ((1-t)(2-y))^2)$$

Solve via separation of variables: $\frac{dy}{dt} = \frac{1}{(1-t)(2-y)}$

$$\int (2-y) dy = \int \frac{dt}{1-t} \text{ implies } 2y - \frac{y^2}{2} = -ln|1-t| + C$$

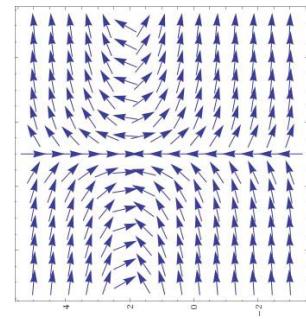

$$y^2 - 4y - 2ln|1-t| + C = 0$$

$$y = \frac{4 \pm \sqrt{16+4(2ln|1-t|+C)}}{2} = 2 \pm \sqrt{4+2ln|1-t|+C}$$

$$y = 2 \pm \sqrt{2ln|1-t|+C}$$

Find domain: $2ln|1-t| + C \geq 0 \ \& \ t \neq 1 \ \& \ y \neq 2$

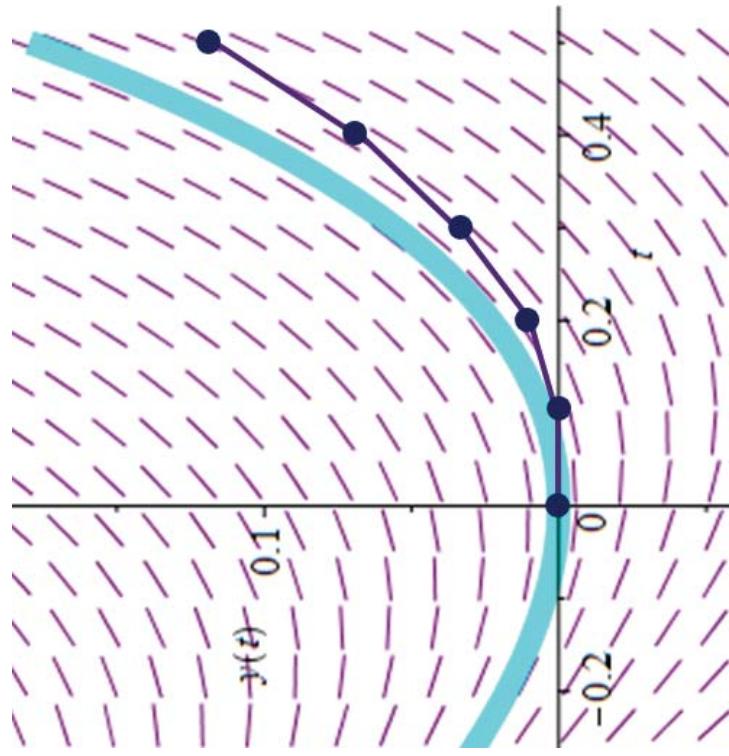

NOTE: the convention in this class to choose the largest possible connected domain where tangent line to solution is never vertical.

2.7: Approximating soln to IVP using multiple tangent lines.

$$\text{Example: } y' = t + 2y, y(0) = 0$$

$$y(t) = \begin{cases} 0 & 0 \leq t \leq 0.1 \\ 0.1t - 0.01 & 0.1 \leq t \leq 0.2 \\ 0.22t - 0.034 & 0.2 \leq t \leq 0.3 \\ 0.364t - 0.0772 & 0.3 \leq t \leq 0.4 \\ 0.5328t - 0.14672 & 0.4 \leq t \leq 0.5 \end{cases}$$

2.8: Approximating soln to IVP using seq of fins,

$$\phi_{n+1}(t) = \int_0^t f(s, \phi_n(s)) ds$$

$$\text{Example: } y' = t + 2y, y(0) = 0$$

$$\begin{aligned} \phi_0(t) &= 0, & \phi_1(t) &= \frac{t^2}{2}, & \phi_2(t) &= \frac{t^2}{2} + \frac{t^3}{3}, \\ \phi_3(t) &= \frac{t^2}{2} + \frac{t^3}{3} + \frac{t^4}{6}, & \phi_4(t) &= \frac{t^2}{2} + \frac{t^3}{3} + \frac{t^4}{6} + \frac{t^5}{15} \end{aligned}$$
